Metrics and Action Group Configuration

Introduction

This document explains how to configure metrics and Action Groups for the Investran environment using Terraform. It describes the two repositories involved and how they relate to each other.

Repositories

- **terraform-investran**: This repository contains the base infrastructure structure. From here, the Terraform code that creates the resources is executed. It includes files such as `appsettings.json` and `terraform-investran`.

- **dev-investran-pcs**: This repository contains the variables. Although `terraform-investran` creates the structure, the variables defined in `dev-investran-pcs` take precedence. Files such as `main` and `locals` are used.

Variable Priority

The variables from the `dev-investran-pcs` repository take priority over those in `terraform-investran`. Therefore, it's important to keep the `main` and `locals` files in the dev environment up to date, as their values are applied when creating the resources.

Action Groups

- `account_team-action-group`

- `architc_team-action-group`

- `busnEvt_team-action-group`

- `coredev_team-action-group`

- `enginer_team-action-group`

- `india_team-action-group`

- `migrant_team-action-group`
